

Empathy Map

HDI Prediction System | SmartBridge AI/ML Internship Project

Persona: policy researcher / government data analyst

Says	Thinks
• "I need HDI data for multiple countries quickly for my report." • "Why does calculating HDI take so many manual steps?" • "I wish I could just enter the indicators and get a score." • "The official HDI report is already a year old by the time it's published."	• This process should be automated with technology available today. • I'm not confident in my manual calculations being fully accurate. • If I had a reliable prediction tool, I could make faster policy recommendations. • Data-driven decisions need real-time or near real-time insights.
Does	Feels
• Downloads HDI datasets from UNDP and other public sources. • Manually normalizes and combines health, education, and income indices. • Cross-checks calculations across spreadsheets, which is repetitive and slow. • Searches online for tools or calculators, often finding none that fit.	• Frustrated by the lack of a simple, accessible prediction tool. • Anxious about deadlines when manual analysis takes too long. • Relieved and confident when a reliable shortcut is available. • Motivated to use data effectively for real-world development planning.

Pain points

- Manual HDI computation is slow, technical, and error-prone.
- Publicly available HDI figures are outdated by the time they're released.
- No accessible tool exists for quick, indicator-based HDI estimation.

Gains (expected from solution)

- Instant HDI prediction from indicator inputs via a simple web interface.
- Faster, more confident, data-driven decision-making for research and policy.
- An accessible tool usable by students, researchers, and analysts alike, with no statistical expertise required.
